CHECKLIST FROM CHECKPOINTS OF:

Usability (Web)

The web usability checklist consists of a set of checkpoints that can be done when developing your website.

You can use this list to confirm that your website complies with these rules and to ensure that you don't forget some important features during development, or even to quickly assess the usability of an existing website.

Navigation and Feedback

✓ Feedback on user actions is always provided

The user must always receive immediate feedback on their actions so that they know that the system has received their command and is processing it. This feedback can be provided in several ways: when the user passes over a link (a: hover); when the user clicks on a link (a: active); when the user navigates with the keyboard (a: focus); when the user is filling out form fields (input[type= text]: focus, textarea: focus); when the user clicks on a link that opens on the same page (#id: target); and/or when the action triggered by the user takes a long time to be processed (progress bar, loading icon or other information that gives the feeling that the action is taking place and that the user should wait for it to finish):

✓ Feedback is provided on the user's location

We must always inform the user's location, preferably through clear visual feedback in the menu, indicating the section in which the user is. This information can also be supplemented with "breadcrumb" navigation in the case of more than 2 hierarchical navigation levels:

✓ Link and menu titles are clear and noticeable

The texts in the menus must be clearly perceptible in such a way that the user can perceive at the outset what contents he will see if he clicks on a particular link. Whenever possible, the use of abbreviations in main menus should be avoided:

✓ Clickable items look clickable and different from the rest of the content

Clickable items must be clearly distinguishable from the remaining items. Links in the middle of the text should be immediately identifiable as such and should not be confused with the rest of the text. Once the aspect of the links has been defined, that aspect must be kept identical on all the remaining pages of the website:

✓ Non-clickable items do not look like links or buttons

The use of underlined texts should be avoided when they do not contain links. Additionally, in the middle of the text, different colors should not be used in words, sentences or paragraphs. A consistency should be maintained whereby the text always maintains the same colour throughout all pages, as the use of text in a different colour may also be associated with the existence of a link to another page. Even more serious is using the same color

A SUA PONTUAÇÃO: 24/28 🍷

chosen for links in text that is not a link (if you do not use underlined links, it is important to identify them with a different color/aspect than the rest of the text).

☒ **Link text makes sense when read out of context**

Users should be able to look at links and automatically perceive something about their destination even before they click. Using terms like "click here" can be quite counterproductive and when read out of context does not provide additional information.

☒ **No broken links**

Links should be tested so that there are no broken links (for non-existent pages, or for incorrect pages)

☒ **There is enough padding in the pagination links**

In paging links, extra spacing (padding) must be created around each link. This makes navigation easier since links placed only in one character become too narrow and difficult to click. By creating this extra spacing, the clickable area on the links increases and at the same time provides better visual feedback to the user.

Layout

☒ **Pages are consistent throughout the website**

Important information and clickable items (main and secondary navigation blocks) should always be placed in the same locations throughout the website.

☐ **There is a specific style sheet for printing**

The website must be prepared so that content can be read online or on paper. According to some studies, the reason users choose to print an article or read it online is its size. The larger the article, the more likely users are to choose to print it rather than read it online. Therefore, the option to print the contents of a web page should always be provided. That option should be effected through a print-specific style sheet (CSS) and not through a link opening the same article in a different (print-optimized) version.

☐ **Fixed heights are not defined for elements**

It is important that the graphic aspect does not limit the contents and that it grows according to the increase of the same or the increase of the text size. Therefore, graphic elements should not have fixed heights, as the content that will be placed inside can grow more than the height set at the start, thus breaking the layout.

☒ **The icons used are consistent with the actions they perform**

Icons should always represent the same actions and should not be repurposed for other different actions throughout the website.

☒ **No decorative images are used in the middle of HTML**

The use of decorative images in the middle of HTML should be avoided (e.g. rounded corners, spacing images, etc.). All elements related to presentation/decoration must be included via CSS. On the other hand, images that

convey important information or that are part of the content should be included directly on the page via the IMG tag and not as a background image of a DIV.

Readability

✔ **Line spacing has been increased to improve readability**

A minimum line spacing of 1.4 points must be maintained in the text blocks of the contents (texts and articles). Greater line spacing helps make text easier to read and reduces the feeling of eye fatigue after reading long texts on the screen. This spacing can be easily added via a line of CSS: line-height:1.4;

✔ **Critical information (which requires the user's attention) is sufficiently prominent on the page**

Critical information can be of various types, but is usually related to information about changed content on the page or validation of data entered by the user in forms. These can be warnings, information, or errors. The highlight effect should not be abused since it is more efficient when used a few times on the page. On a website where the user is constantly confronted with highlight text, the effect of attracting the user's attention is easily lost.

✔ **Only bold blocks of text are used to highlight relevant information on the page**

Excessive use of bold text should be avoided. The text a bold should only be used to highlight certain words or phrases. Overuse causes the emphasis we want to place on the elements we have highlighted to lose its effect. If everything is highlighted, nothing stands out.

✔ **There is sufficient contrast between the color of the texts and the background color**

The colour used in texts should make a sufficient contrast with the background colour to ensure good readability. A poor contrast between the two colors can make texts unreadable to a good portion of the population, even for people with "normal" vision.

Forms and Messages

✔ **Compulsory completion items are distinguishable from the rest**

Users must be able to clearly distinguish the fields in which completion is mandatory from the other fields. Today, most websites use an asterisk in front of the field name to identify them as required; other websites use the word "required" instead of the asterisk. Both solutions are valid, but using an asterisk requires a caption at the top of the form to indicate that fields marked with * are required to be completed.

✔ **Error messages are next to the elements that contain the error**

Error messages must be indicated next to the fields containing the error and not just at the top or bottom of the form. This allows you to better contextualize errors and helps you understand where users need to correct them.

✔ **The main actions are clearly distinguishable from the secondary actions in the forms**

There has to be a visual differentiation between the main actions and the secondary actions so as to avoid

potential errors by the user. This differentiation also helps to clearly understand which action confirms and which action cancels the form.

☒ **Forms are working and send to the correct containers**

The forms must all be tested and the data receipt accounts must be checked to confirm that the data has been successfully received.

☒ **Search is working and error messages are adequate**

The search form must return results for the searches made and when there are no results a message must be shown to indicate that the search has not returned results.

Help

☒ **There is contextual help in the most complex interactions**

Since most people don't usually read the instructions/help before starting to use a system, the most useful way to help users navigate and navigate situations that may be more complicated is to provide contextual help, at the right time and in the right place, where we know users will need it.

☒ **Error messages help solve the problem**

Error messages should be clear and should help the user correct the error. A message like: "An error occurred while filling out the form" does nothing to help you know why the error occurred or how to fix it.

Social Networks

☒ **"Open Graph" tags have been added**

Open Graph tags should be added at the beginning of all content pages that allow you to indicate a series of parameters about the page content and that will be used in social media shares.

Responsive

☒ **The site has been tested on devices of various sizes**

When developing responsive websites, they should be tested on multiple devices with different screen sizes to confirm that the layouts are correctly applied.

Performance

☐ **All static files have been minified and compressed**

All static files (e.g. CSS, JS and HTML) must be minified and compressed. This allows you to save a lot of KB

A SUA PONTUAÇÃO: 24/28 🍷

every time the pages are loaded.

☐ **The contents have been optimized for mobile**

It's important to ensure that the content a responsive website loads is optimized to be consumed under these circumstances. This includes serving lighter images, replacing Flash elements (if any) with HTML5 equivalents (e.g. video players), and reducing decorative elements to as few items and files as possible.
